ROUGH DRAFT

Beneath the Mesa

Assessing Aquifer, Well, and Acequia Water Resources Across Sandoval County, New Mexico

A County-Scale Screening Study with Cuba, New Mexico as a Focus Area

Petar Djordjevic, Dylan Gonzales, James Wanueka, Micah Watkins, and Meckrem Yousef

ABSTRACT
Water scarcity is a persistent challenge across New Mexico. Sandoval County spans several hydrogeologic settings, and its communities depend on a mix of groundwater wells, surface water, and acequia irrigation systems. This project evaluates the condition and long-term viability of those water resources across the county, with Cuba, New Mexico, on the eastern edge of the San Juan Basin, as a focused case study. The project is motivated by concern about declining groundwater near Cuba, but rather than assume how severe that decline is or what is causing it, we test what the available public data actually show. *[Add the data used, the main findings, and what they mean, in three to four sentences, once the analysis is complete.]*

1 Introduction

1.1 Background and Motivation

[Background on water resources in New Mexico and Sandoval County, and the concern about declining groundwater near Cuba that motivated the project.]

1.2 Approach

The study works at two levels:

- **County-wide screening.** Map and compare aquifers, wells, water levels, water quality, and acequia and surface-water features across Sandoval County. Because the county crosses several geologic regions, comparisons are grouped by region or aquifer system instead of treating the county as one uniform aquifer.
- **Cuba case study.** A closer look at the Ojo Alamo Sandstone and San Jose Formation near Cuba, using San Juan Basin aquifer datasets alongside nearby well, water-level, and water-quality records.

1.3 Research Questions

RQ1. How do groundwater levels vary across Sandoval County, and which areas show sustained decline, stability, or recovery?

RQ2. What do well records show about well depth, depth to water, and the aquifer units that communities rely on?

RQ3. Do the available data support the concern that Cuba's main groundwater source is approaching severe depletion?

RQ4. How do the Ojo Alamo Sandstone and San Jose Formation compare near Cuba in extent, thickness, hydraulic properties, water levels, and water quality?

RQ5. How does groundwater quality, including salinity, vary across the county and near Cuba?

RQ6. Where are acequias located, what surface water do they depend on, and which communities do they serve?

RQ7. Do changes in groundwater levels line up with nearby surface-water or acequia conditions, or are the records too limited to tell?

RQ8. Where is monitoring coverage strong, and where are the most important data gaps?

RQ9. Which indicators can be combined into a dashboard that shows water-resource stress without

Figure 1 (to be added by the analysis lead): county map showing wells, water-level measurements, major aquifer and geologic regions, and acequias, with Cuba marked.

Figure 1. *[Caption to be written.]*

overstating how certain the data are?

2 Study Area

2.1 Sandoval County

[Describe the county, its hydrogeologic settings, and its main communities and water sources (Fig. 1).]

2.2 Cuba Focus Area

Cuba lies on the eastern edge of the San Juan Basin. The case study focuses on the Ojo Alamo Sandstone and San Jose Formation near Cuba (U.S. Geological Survey, 2020; Kernodle, 1996). *[Describe Cuba, its water supply, and the aquifers it draws from, and define the boundaries of the focus area.]*

3 Data

Town-specific data for Cuba are limited, so the study relies on broader public datasets that can be filtered geographically.

3.1 Datasets Used

USGS monitoring statistics. USGS monthly and yearly statistics for 30 monitoring sites in Sandoval County (17 stream gages, 9 wells, 2 canals, and 2 reservoirs), with records from 1926 to 2026. The file covers streamflow, depth to groundwater, reservoir storage, suspended sediment, water temperature, and water-quality measures: specific conductance, dissolved oxygen, pH, and turbidity. *[Source to be added.]*

OSE aquifer tests. New Mexico Office of the State Engineer aquifer-test records, 3,455 statewide and 179 in Sandoval County, including well depth, screened interval, geologic formation, and hydraulic properties such as transmissivity and storativity. *[Source to be added.]*

3.2 Datasets to Be Collected

- **Aquifer geometry near Cuba:** USGS San Juan Basin digital aquifer data for the Ojo Alamo Sandstone and San Jose Formation (U.S. Geological Survey, 2020).
- **Water quality and salinity:** the San Juan Basin Brackish Water Assessment (New Mexico Bureau of Geology and Mineral Resources, 2026b) and New Mexico Water Data records (New Mexico Water Data, 2026).
- **Acequias:** locations and service areas of acequias and community ditches (New Mexico Interstate Stream Commission, 2026).
- **More water-level records:** the National Ground-Water Monitoring Network (U.S. Geological Survey, 2026) and the Healy Collaborative Groundwater Monitoring Network (New Mexico Bureau of Geology and Mineral Resources, 2026a).
- **County boundary:** a Sandoval County boundary layer to organize the maps.

[Data acquisition lead: explain why each dataset was chosen and which research questions it answers.]

4 Methods

4.1 Data Cleaning

Raw downloads are kept unedited in the repository. Each cleaned file is made by a script that reads the raw file and writes the cleaned one, so anyone can rerun it and get the same result. All cleaned files share the same columns for site ID, site name, latitude, longitude, date, and source, with one row per measurement and missing values left blank. *[Data cleaning lead: describe each cleaning step, the decisions made, and the final row counts.]*

4.2 Analysis

The analysis focuses on measurable indicators, such as depth to water, water-level change over time, well depth, aquifer unit, and salinity, rather than a full hydrologic model. Where records are sparse, the results say so instead of filling the gaps. *[Analysis lead: describe the method used for each research question.]*

4.3 Classifying Findings

Each finding is labeled as one of the following:

- **Measured:** a trend or pattern the data show directly.

Figure 2 (to be added): time series of groundwater levels for wells with repeated measurements.

Figure 2. *[Caption to be written.]*

- **Hypothesis:** a possible explanation the data are consistent with but don't prove.
- **Insufficient data:** a question the available records can't answer yet.

4.4 Interactive Dashboard

Results are presented in an interactive Streamlit dashboard built with pandas and Plotly. Code and documentation are maintained on GitHub (Djordjevic et al., 2026). *[Dashboard lead: describe each page of the app and what a visitor can do there.]*

5 Results

5.1 Groundwater Levels

[RQ1 (Fig. 2).]

5.2 Wells and Aquifer Units

[RQ2.]

5.3 Cuba Case Study

[RQ3 and RQ4.]

5.4 Water Quality

[RQ5.]

5.5 Acequias and Surface Water

[RQ6 and RQ7.]

5.6 Monitoring Coverage and Data Gaps

[RQ8.]

6 Discussion

[What the results mean for Sandoval County and Cuba, and which indicators best communicate water-resource stress (RQ9).]

7 Limitations

[Data gaps and what the data can't support.]

8 Conclusions

[Summary of findings and recommended next steps.]
